# Section 6.3

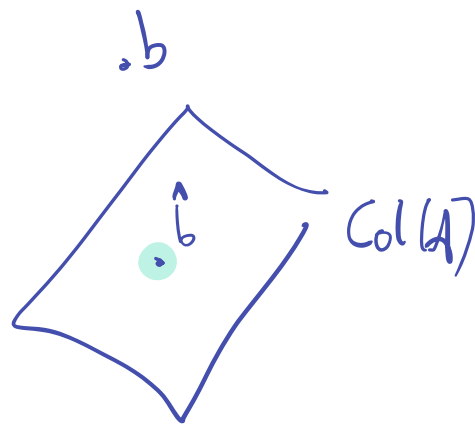

## Orthogonal projection

# Orthogonal Projections

**Theorem.** Let  $W = \text{Col}(A)$ . For any vector  $b$  in  $\mathbb{R}^n$ , the equation

$$A^T A x = A^T b$$

is consistent and the orthogonal projection  $b_W$  is equal to  $Ax$  where  $x$  is any solution.

$$\hat{b} = A \hat{x}$$

where  $\hat{x}$  is a soln to  $A^T A x = A^T b$

# Orthogonal Projections

Let  $b$  be a vector in  $\mathbb{R}^n$  and  $W$  a subspace of  $\mathbb{R}^n$ .

The **orthogonal projection** of  $b$  onto  $W$  is the vector obtained by drawing a line segment from  $b$  to  $W$  that is perpendicular to  $W$ .

**Fact.** The following three things are all the same:

- The orthogonal projection of  $b$  onto  $W$
- The vector  $b_W$  (the  $W$ -part of  $b$ ) **algebra!**
- The closest vector in  $W$  to  $b$  **geometry!**

# Orthogonal Projections

$$A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 0 \end{pmatrix}$$

Example. Find  $b_W$  if  $b = \begin{pmatrix} 6 \\ 5 \\ 4 \end{pmatrix}$ ,  $W = \text{Span} \left\{ \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix} \right\}$

Steps. Find  $A^T A$  and  $A^T b$ , then solve for  $x$ , then compute  $Ax$ .

$$\textcircled{1} A^T A = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$$

$$\textcircled{2} A^T b = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix} \begin{pmatrix} 6 \\ 5 \\ 4 \end{pmatrix} = \begin{pmatrix} 10 \\ 11 \end{pmatrix}$$

$$\textcircled{3} \left( \begin{array}{cc|c} 2 & 1 & 10 \\ 1 & 2 & 11 \end{array} \right) \rightsquigarrow \left( \begin{array}{cc|c} 1 & 2 & 11 \\ 2 & 1 & 10 \end{array} \right) \rightsquigarrow \left( \begin{array}{cc|c} 1 & 2 & 11 \\ 0 & -3 & -12 \end{array} \right) \rightarrow \left( \begin{array}{cc|c} 1 & 2 & 11 \\ 0 & 1 & 4 \end{array} \right)$$

$$(A^T A \mid A^T b)$$

$$\textcircled{4} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 3 \\ 4 \end{pmatrix} = \begin{pmatrix} 7 \\ 4 \\ 3 \end{pmatrix} \rightsquigarrow \left( \begin{array}{cc|c} 1 & 0 & 3 \\ 0 & 1 & 4 \end{array} \right)$$

Question. How far is  $b$  from  $W$ ?

$$\|b_W^\perp\| = \|b - b_W\| = \left\| \begin{pmatrix} -1 \\ 1 \\ 1 \end{pmatrix} \right\| = \sqrt{(-1)^2 + 1^2 + 1^2} = \sqrt{3}$$

# Properties of projection matrices

Let  $W$  be a subspace of  $\mathbb{R}^n$  and let  $T : \mathbb{R}^n \rightarrow \mathbb{R}^n$  be the function given by  $T(b) = b_W$  (orthogonal projection). Let  $A$  be the standard matrix for  $T$ . Then

- The 1-eigenspace of  $A$  is  $W$  (unless  $W = 0$ )
- The 0-eigenspace of  $A$  is  $W^\perp$  (unless  $W = \mathbb{R}^n$ )

- $A^2 = A$

- $\text{Col}(A) = W$

- $\text{Nul}(A) = W^\perp$

- $A$  is diagonalizable; its diagonal matrix has  $m$  1's &  $n - m$  0's where  $m = \dim W$  (this gives another way to find  $A$ )

diagonalizable; sum of dims of eigenspaces is  $n$ .  
and:  $\dim W + \dim W^\perp = n$ .

You can check these properties for the matrix in the last example. It would be very hard to prove these facts without any theory. But they are all easy once you know about linear transformations!

# Section 6.5

## Least Squares Problems

# Least Squares problems

What if we can't solve  $Ax = b$ ? How can we solve it as closely as possible?

To solve  $Ax = b$  as closely as possible, we orthogonally project  $b$  onto  $\text{Col}(A)$ ; call the result  $\hat{b}$ . Then solve  $Ax = \hat{b}$ . This is the *least squares solution* to  $Ax = b$ .

# Outline of Section 6.5

- The method of least squares
- Application to best fit lines/planes
- Application to best fit curves

# Least squares solutions

$A = m \times n$  matrix.

A **least squares solution** to  $Ax = b$  is an  $\hat{x}$  in  $\mathbb{R}^n$  so that  $A\hat{x}$  is as close as possible to  $b$ , this means  $A\hat{x} = \hat{b}$ .

The error is  $\|A\hat{x} - b\|$ .

In last section we wanted  $\hat{b}$ .  
Now we want  $\hat{x}$ .

Solve  $A^T A x = A^T b$   
(like before)

but don't multiply  
the answer by  $A$ .

▶ Demo

# Least squares solutions

A **least squares solution** to  $Ax = b$  is an  $\hat{x}$  in  $\mathbb{R}^n$  so that  $A\hat{x}$  is as close as possible to  $b$ .

The error is  $\|A\hat{x} - b\|$ .  $\|b_{w^\perp}\|$   
distance from  $\hat{b}$  to  $b$ .

**Theorem.** The least squares solutions to  $Ax = b$  are the solutions to

$$(A^T A)x = (A^T b)$$

So this is just like what we did before when we were finding the projection of  $b$  onto  $\text{Col}(A)$ . But now we just solve and don't (necessarily) multiply the solution by  $A$ .

# Least squares solutions

## Example

**Theorem.** The least squares solutions to  $Ax = b$  are the solutions to

$$(A^T A)x = (A^T b)$$

Find the least squares solutions to  $Ax = b$  for this  $A$  and  $b$ :

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \quad b = \begin{pmatrix} 6 \\ 0 \\ 0 \end{pmatrix}$$

What is the error?

# Least squares solutions

$$b - \hat{b} = b_w^\perp$$

$$\textcircled{5} \hat{b} = A\hat{x} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \begin{pmatrix} -3 \\ 5 \end{pmatrix} = \begin{pmatrix} 5 \\ 2 \\ -1 \end{pmatrix}$$

$$\|b - \hat{b}\| = \left\| \begin{pmatrix} 1 \\ -2 \\ 1 \end{pmatrix} \right\|$$

Example

$$\text{Formula: } (A^T A)x = (A^T b)$$

Find the least squares solution/error to  $Ax = b$ :

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \quad b = \begin{pmatrix} 6 \\ 0 \\ 0 \end{pmatrix}$$

$$= \sqrt{1^2 + (-2)^2 + 1^2}$$

$$= \sqrt{6} \leftarrow \text{error.}$$

$$\textcircled{1} A^T A = \begin{pmatrix} 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} = \begin{pmatrix} 5 & 3 \\ 3 & 3 \end{pmatrix}$$

$$\textcircled{2} A^T b = \begin{pmatrix} 0 & 1 & 2 \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 6 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 6 \end{pmatrix}$$

$$\textcircled{3} \left( \begin{array}{cc|c} 5 & 3 & 0 \\ 3 & 3 & 6 \end{array} \right) \rightsquigarrow \left( \begin{array}{cc|c} 1 & 1 & 2 \\ 5 & 3 & 0 \end{array} \right) \longrightarrow \left( \begin{array}{cc|c} 1 & 1 & 2 \\ 0 & -2 & -10 \end{array} \right) \longrightarrow \left( \begin{array}{cc|c} 1 & 1 & 2 \\ 0 & 1 & 5 \end{array} \right) \longrightarrow \left( \begin{array}{cc|c} 1 & 0 & -3 \\ 0 & 1 & 5 \end{array} \right)$$

$$\textcircled{4} \text{Answer: } \hat{x} = \begin{pmatrix} -3 \\ 5 \end{pmatrix} \quad (\text{Don't multiply by } A)$$

# Least squares solutions

**Theorem.** Let  $A$  be an  $m \times n$  matrix. The following are equivalent:

1.  $Ax = b$  has a unique least squares solution for all  $b$  in  $\mathbb{R}^m$
2. The columns of  $A$  are linearly independent
3.  $A^T A$  is invertible

In this case the least squares solution is  $(A^T A)^{-1}(A^T b)$ .

# Application

## Best fit lines

Eqn of line:  $y = Mx + B$ . Want  $M, B$ .

Problem. Find the best-fit line through  $(0, 6)$ ,  $(1, 0)$ , and  $(2, 0)$ .

$$(0, 6): 6 = M \cdot 0 + B \cdot 1$$

$$(1, 0): 0 = M \cdot 1 + B \cdot 1 \rightsquigarrow$$

$$(2, 0): 0 = M \cdot 2 + B \cdot 1$$

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \\ 2 & 1 \end{pmatrix} \quad b = \begin{pmatrix} 6 \\ 0 \\ 0 \end{pmatrix}$$

$$x = \begin{pmatrix} M \\ B \end{pmatrix}$$

No soln! No line going thru all 3.

▶ Demo

We already found the least squares soln:

$$\hat{x} = \begin{pmatrix} -3 \\ 5 \end{pmatrix} = \begin{pmatrix} M \\ B \end{pmatrix}$$

Best fit line:  $y = -3x + 5$ .

# Best fit lines

## Poll

What does the best fit line minimize?

1. the sum of the squares of the distances from the data points to the line
2. the sum of the squares of the vertical distances from the data points to the line
3. the sum of the squares of the horizontal distances from the data points to the line
4. the maximal distance from the data points to the line

# Least Squares Problems

## More applications

Determine the least squares problem  $Ax = b$  to find the best parabola  $y = Cx^2 + Dx + E$  for the points:

$$(0, 0), (2, 0), (3, 0), (0, 1)$$

plug in pts  $\rightsquigarrow$  4 eqns in  
3 vars  $(C, D, E)$ .

▶ Demo

# Least Squares Problems

## More applications

Determine the least squares problem  $Ax = b$  to find the best fit ellipse  $Cx^2 + Dxy + Ey^2 + Fx + Gy + H = 0$  for the points:

$$(0, 0), (2, 0), (3, 0), (0, 1)$$

Gauss invented the method of least squares to predict the orbit of the asteroid Ceres as it passed behind the sun in 1801.

# Least Squares Problems

## Best fit plane

Determine the least squares problem  $Ax = b$  to find the best fit linear function  $f(x, y) = Cx + Dy + E$

$x$	$y$	$f(x, y)$
1	0	0
0	1	1
-1	0	3
0	-1	4

## Summary of Section 6.5

- A **least squares solution** to  $Ax = b$  is an  $\hat{x}$  in  $\mathbb{R}^n$  so that  $A\hat{x}$  is as close as possible to  $b$ .
- The error is  $\|A\hat{x} - b\|$ .
- The least squares solutions to  $Ax = b$  are the solutions to  $(A^T A)x = (A^T b)$ .
- To find a best fit line/parabola/etc. write the general form of the line/parabola/etc. with unknown coefficients and plug in the given points to get a system of linear equations in the unknown coefficients.

## Typical Exam Questions 6.5

- Find the best fit line through  $(1, 0)$ ,  $(2, 1)$ , and  $(3, 1)$ . What is the error?
- Find the best fit parabola through  $(1, 0)$ ,  $(2, 1)$ ,  $(3, 1)$ , and  $(3, 0)$ . What is the error?
- True/false. For every set of three points in  $\mathbb{R}^2$  there is a unique best fit line.
- True/false. If  $\hat{x}$  is the least squares solution to  $Ax = b$  for an  $m \times n$  matrix  $A$ , then  $\hat{x}$  is the closest point in  $\mathbb{R}^n$  to  $b$ .
- True/false. If  $\hat{x}$  and  $\hat{y}$  are both least squares solutions to  $Ax = b$  then  $\hat{x} - \hat{y}$  is in the null space of  $A$ .
